1. Explain behaviour of hub device

A Hub is layer 1 device. When data is received on one port the hub forwards it to all other ports. It does not check destination MAC address. It works as broadcast casting. It normally operates in half-duplex mode. Its work in bus topology.

2. Explain behaviour of switch device

It is a layer 2 device. It is used to connect multiple network devices. It is also ~~do broadcast~~ broadcast + unicast. It contains a MAC table. It stores MAC addresses in its MAC address table. It is called a single broadcast domain. When data arrives, it checks the destination MAC address. If the destination MAC is known, it forwards the data only to the required port. If it is unknown, it broadcasts the data to other ports.

3. Explain behaviour of router device

It is a layer 3 device. It connects different networks. It is a unicast device. It is used to break the broadcast domain. A router contains a routing table to send data. The routing table contains a list of routes.
